=> d ab

L2 ANSWER 1 OF 51 CAPLUS COPYRIGHT 2005 ACS on STN
 AB This invention provides two **rice** stress-inducible promoters,; and use in generating environmental stress-tolerant plants. Structural gene or regulatory gene that enhances stress-tolerance may be operably linked to the promoter and introduced into plants. Δ 1-Pyrroline-5-carboxylate synthetase (P5CS) gene, galactinol synthase gene AtGolS3, **Arabidopsis** transcription factor DREB (dehydration-responsive element binding) gene, **rice** DREB homolog OsDREB gene, abscisic acid (ABA) biosynthesis enzyme 9-cis-epoxycarotenoid dioxygenase (NCED), in particular can be linked to the promoter and expressed. In **rice**, the authors isolated promoter regions for two stress-inducible genes: a022 (LIP9) and a066 (WSI724). The LIP9 or WSI724 induced the transcription of the GUS reporter gene in **rice** and tobacco, in response to drought, high-salt, and/or cold stresses. Expression of LIP9 or WSI724 genes was elevated in transgenic **rice** carrying OsDREB1A or DREB1C genes. These promoters are potentially useful for producing transgenic monocots that are tolerant to drought, high-salt, and/or cold stresses.

L2 ANSWER 2 OF 51 CAPLUS COPYRIGHT 2005 ACS on STN

AB Synthetic transcription factors including a domain binding a CCG sequence in the regulatory region of a plant gene are described. The preferred domains are AP2 domains from plant C-repeat/DRE binding factors. When these proteins are present at high levels, the plant exhibits increased tolerance to environmental stresses such as cold, freezing, drought or high salinity. This is achieved by increasing the plant biomass and levels of a cell protectant in a plant, such as sucrose or proline. The genes were identified by screening cDNA libraries from stressed *Arabidopsis thaliana* for C-repeat/DRE binding proteins using a two hybrid assay system.

- AB Proline and quaternary ammonium compds. (QAC), in addition to being N-rich, are known to accumulate in plants under different environmental stress conditions. The accumulation of N-rich compds. in plants has been shown to confer stress resistance. The aim of our work is two-fold:.. First, to study the influence of temperature on proline, QAC, and choline metabolism in tomato leaves; and. Second, to investigate the relationship between N source applied (NO₃⁻ or NH₄⁺) and thermal stress resistance in these plants. To do this, expts. were conducted at three different temps. (10°C, 25°C, 35°C); at each temperature half of the plants received NO₃⁻, and the other half received NH₄⁺. At 35°C the plants had the lowest biomass production with respect to 25°C (optimal temperature) and 10°C (cold stress), suggesting that tomato plants were most affected by heat stress. At 35°C, there were also high levels of choline and proline due to the activation of $\Delta 1$ -pyrroline-5-carboxylate synthetase (**P5CS**) and ornithine aminotransferase (OAT), and simultaneous inhibition of **proline dehydrogenase** (PDH) and proline oxidase (PO). However, plants with NH₄⁺ as the N source exhibited reduced growth with respect to the plants fed with NO₃⁻. This is interesting because, under heat stress (35°C), biomass production, as well as proline and choline accumulation, in NH₄⁺ fed plants was higher than in NO₃⁻ fed plants. From this, we concluded that tomato plants fed with NH₄⁺ as the N source show higher tolerance to heat stress (35°C) than plants fed with NO₃⁻.

AB The effects of salt stress were studied on the accumulation and metabolism of proline and its correlation with Na⁺ and K⁺ content in shoots and callus tissue of four potato cultivars, viz., Agria, Kennebec (relatively salt tolerant), Diamant and Ajax (relatively salt sensitive). Na⁺ and proline contents increased in all cultivars under salt stress. However, K⁺ and protein contents decreased in response to NaCl treatments. The activities of enzymes involved in proline metabolism, Δ^1 -pyrroline-5-carboxylate synthetase (P5CS) and proline dehydrogenase (ProDH) increased and decreased, resp., in response to elevated NaCl concns. The changes of P5CS and ProDH activities in more salt sensitive cultivars (Diamant, Ajax) were more than those in the tolerant ones. Then the stimulation of synthesis in combination with a partially increase of protein proteolysis, a decrease in proline utilization and inhibition of oxidation resulted in high proline contents in seedlings and calli under salt stress. In callus tissue, reduced growth and cell size may be partially responsible for high proline accumulation in response to high NaCl levels. However, although the basic proline contents in the seedlings of more salt tolerant cultivars were higher than the sensitive ones, a clear relationship was not generally observed between accumulation of proline and salt tolerance in potato.
